

3.4

Subtyping and Inheritance in C++

2018/9/6 Data Structures © Prof. Ren-Song Tsay 129

Object Inheritance

- An object A could be used to define another object B.
- Both objects and operations of A are automatically inherited by B.
 - **house** can inherit from **building**
- Advantages:
 - Simplification of software development
 - Easy to test and debug
 - Reusability
 - Flexibility

2018/9/6 Data Structures © Prof. Ren-Song Tsay 130

C++ Inheritance

- Define a class in terms of another class
 - easier to create and maintain an application.
- The existing class = **base** class, the new class = **derived** class.
- The **derived** class *is a* **base** class
 - dog IS-A mammal
- A class can be derived from more than one classes, i.e. inherit data and functions from multiple base classes.

2018/9/6 Data Structures © Prof. Ren-Song Tsay 131

Process Geometry

- If to develop a program to process various types of geometry.

Triangle

Rectangle

Trapezoid

...

- Operations on these primitives:
 - Get number of vertices.
 - Calculate the area of the primitive.
 - Check whether it is convex or not.

2018/9/6 Data Structures © Prof. Ren-Song Tsay 132

Implement Using Classes

```

class Triangle {
public:
    Triangle () {
        m_VN = 3;
        mp_V = new Point [m_VN];
    }
    ~Triangle () {
        delete [] mp_V;
        mp_V = NULL;
    }
    double CalArea ();
    bool isConvex();
    int vtxNum() { return m_VN; }
private:
    int m_VN;
    Point* mp_V;
};
                
```

```

class Rectangle {
public:
    Rectangle () {
        m_VN = 4;
        mp_V = new Point [m_VN];
    }
    ~Rectangle () {
        delete [] mp_V;
        mp_V = NULL;
    }
    double CalArea ();
    bool isConvex();
    int vtxNum() { return m_VN; }
private:
    int m_VN;
    Point* mp_V;
};
                
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 133

What's the Problem?

- Duplicated codes in both classes!
- If need to design 100 or more types of geometry?
- If need to add another "common" data member or function?
- Will need to maintain all the classes!

2018/9/6 Data Structures © Prof. Ren-Song Tsay 134

Polygon Base Class

- Polygon is an abstract type of geometry.
- Triangle and rectangle are special polygons.
- But how do we let the triangle and rectangle classes share the same code through using polygon?
- Don't worry! C++ will be your lifesaver!

2018/9/6 Data Structures © Prof. Ren-Song Tsay 135

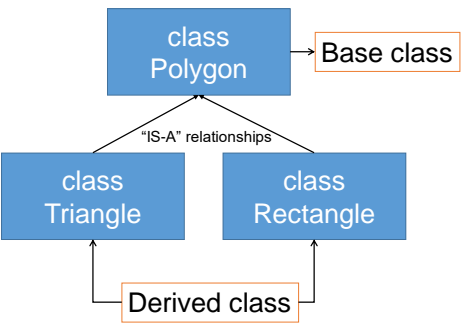

Class Inheritance in C++

- A mechanism to relate one class object to another one.
- Define a "IS-A" relationships between objects.
 - **Type B IS-A** data type of **Type A** if B is a **specialized** version of A and A is more **general** than B, e.g., Triangle IS-A Polygon and Rectangle IS-A Polygon.
- Members (data and functions) in Type A are implicitly copied to Type B.
- Reusability of code

2018/9/6 Data Structures © Prof. Ren-Song Tsay 136

3.4

Class Diagram of Inheritance

```

classDiagram
    class Polygon
    class Triangle
    class Rectangle
    Polygon <|-- Triangle
    Polygon <|-- Rectangle
  
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 137

3.4 Inherit the Polygon Class

```

class Polygon {
public:
    Polygon () {
        m_VN = 0;
        mp_V = NULL;
    }
    ~Polygon () {
        delete [] mp_V;
        mp_V = NULL;
    }
    double CalArea () { return 0.0; }
    bool isConvex() { return true; }
    int vtxNum() { return m_VN; }
protected:
    int m_VN;
    Point* mp_V;
};

class Triangle: public Polygon {
public:
    Triangle () {
        m_VN = 3;
        mp_V = new Point [m_VN];
    }
    ~Triangle () {}
    double CalArea ();
};

Class Rectangle: public Polygon {
public:
    Rectangle () {
        m_VN = 4;
        mp_V = new Point [m_VN];
    }
    ~Rectangle () {}
    double CalArea ();
};
    
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 138

Access Specifier of Inheritance

- “class Triangle: public Polygon” indicates the triangle class inherits *all the non-private members (data and functions)* from Polygon
- The access specifier could be **public**, **protected** and **private**.

<https://www.learncpp.com/cpp-tutorial/115-inheritance-and-access-specifiers/>

2018/9/6 Data Structures © Prof. Ren-Song Tsay 139

Access Specifier: public

Base Class	Derived Class
<pre> class Polygon { private: int x; protected: int y; public: int z; }; </pre>	<pre> class Triangle : public Polygon { private: //CANNOT ACCESS private member of base class protected: int y; public: int z; }; </pre>

2018/9/6 Data Structures © Prof. Ren-Song Tsay 140

Access Specifier: protected

Base Class	Derived Class
<pre> class Polygon { private: int x; protected: int y; public: int z; }; </pre>	<pre> class Triangle : protected Polygon { private: protected: int y; int z; public: }; </pre>

2018/9/6 Data Structures © Prof. Ren-Song Tsay 141

Access Specifier: private

Base Class	Derived Class
<pre> class Polygon { private: int x; protected: int y; public: int z; }; </pre>	<pre> class Triangle : private Polygon { private: protected: int y; int z; public: }; </pre>

2018/9/6 Data Structures © Prof. Ren-Song Tsay 142

Specialization

- Some members (data and functions) are **specialized** in different class.
 - Triangle and Rectangle use different area calculation, e.g., specialized CalArea() function.
- Put these non-common members in private block of base class. Derived class thus cannot access these members (Optional)
- Re-declare the members (data and functions) in the derived class. (**overriding**)

2018/9/6 Data Structures © Prof. Ren-Song Tsay 143

Overriding

```

class Polygon {
public:
    ...
    double CalArea () { return 0.0; }
    ...
};

class Triangle : public Polygon {
public:
    ...
    // overriding CalArea function
    double CalArea () {
        // calculate triangle area
    }
};

class Rectangle : public Polygon {
public:
    ...
    // overriding CalArea function
    double CalArea () {
        // calculate rectangle area
        /* if you want to access the
        original base class function*/
        Polygon::CalArea();
    }
};
    
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 144

Overloading v.s. Overriding

- Function **overloading**:
 - Two or more functions with the **same name** but **different signatures** in the same scope or one in base class and another in derived class.
- Function **overriding**:
 - A **different implementation** of the **same function** in the inherited class.
 - Functions would have the **same signature**, but **different implementation**.
 - Only exist in class inheritance.

<http://www.codeproject.com/Articles/16407/METHOD-Overload-Vs-Overriding>

2018/9/6 Data Structures © Prof. Ren-Song Tsay 145

Initialization

- The order of calling constructors:

```

Base class → 1st derived class → 2nd derived class → Last derived class
            
```
- The order of calling destructors:

```

Last derived class → 2nd derived class → 1st derived class → Base class
            
```
- Use Initialization Lists to initialize base class in derived class via constructor

2018/9/6 Data Structures © Prof. Ren-Song Tsay 146

A Constructor Example

```

class Foo
{
public:
    Foo() { std::cout << "Foo's
        constructor" << std::endl; }
};

class Bar: public Foo
{
public:
    Bar() { std::cout << "Bar's
        constructor" << std::endl; }
};

int main(){
    Bar bar;
}

Output:
Foo's constructor
Bar's constructor
    
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 147

Polymorphism

- A mechanism allow you to **manipulate different objects** through the **common interface**.
- Why not **function overloading**?

```

class Foo
{
public:
    char* getName()
    { return "foo"; }
};

class Bar: public Foo
{
public:
    char* getName()
    { return "Bar"; }
};

class Car: public Foo
{
public:
    char* getName()
    { return "Car"; }
};
    
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 150

Review Function Overloading

```

int main(){
    Foo myFoo;
    Bar myBar;
    Car myCar;

    processObj(myFoo);
    processObj(myBar);
    processObj(myCar);

    processObj(Foo_obj)
    {..._obj.getName()...}

    processObj(Bar_obj)
    {..._obj.getName()...}

    processObj(Car_car)
    {..._obj.getName()...}
}
    
```

- Each function performs the **same algorithm** and works only on **different data type** of object .
- Duplicated code.
- What if need to modify the algorithm?

2018/9/6 Data Structures © Prof. Ren-Song Tsay 151

Polymorphism

```
class Foo
{
public:
char*
getName()
{ return "foo"; }
};
```

```
class Bar : public Foo
{
public:
char*
getName()
{ return "Bar"; }
};
```

```
class Car : public Foo
{
public:
char*
getName()
{ return "Car"; }
};
```

```
int main(){
    Foo* myFoo = new Foo;
    Foo* myBar = new Bar;
    Foo* myCar = new Car;

    processObj(myFoo);
    processObj(myBar);
    processObj(myCar);
}
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 152

Polymorphism

```
class Foo
{
public:
virtual char*
getName()
{ return "foo"; }
};
```

```
class Bar: public Foo
{
public:
virtual char*
getName()
{ return "Bar"; }
};
```

```
class Car: public Foo
{
public:
virtual char*
getName()
{ return "Car"; }
};
```

```
int main(){
    Foo* myFoo = new Foo;
    Foo* myBar = new Bar;
    Foo* myCar = new Car;

    processObj(myFoo);
    processObj(myBar);
    processObj(myCar);
}
```

2018/9/6 Data Structures © Prof. Ren-Song Tsay 153

Polymorphism

Function Overloading

- Data type is determined in **compiler time**.

```
int main(){
    Foo myFoo;
    Bar myBar;
    Car myCar;

    processObj(myFoo);
    processObj(myBar);
    processObj(myCar);
}
```

Dynamic Binding

- Data type is determined in **run time**.

```
int main(){
    Foo* myFoo = new Foo;
    Foo* myBar = new Bar;
    Foo* myCar = new Car;

    processObj(myFoo);
    processObj(myBar);
    processObj(myCar);
}
```

Use the keyword **"virtual"** as a prefix of your member function
